Applications

- Automotive Navigation

The S1722DR8 GNSS Dead-Reckoning receiver module combines GNSS position data, gyroscope data (measuring turning angle), and odometer data (measuring distance traveled) to formulate position solution. This enables accurate navigation solution in poor signal environment or signal blocked area such as inside tunnels. The S1722DR8 is ideal for applications requiring accurate continuous navigation with 100% availability.

The Extended Kalman Filter algorithm combines GNSS and sensor data with weighting function dependent on GNSS signal quality. In poor signal reception area and multipath environment, the position error is reduced by dead reckoning.

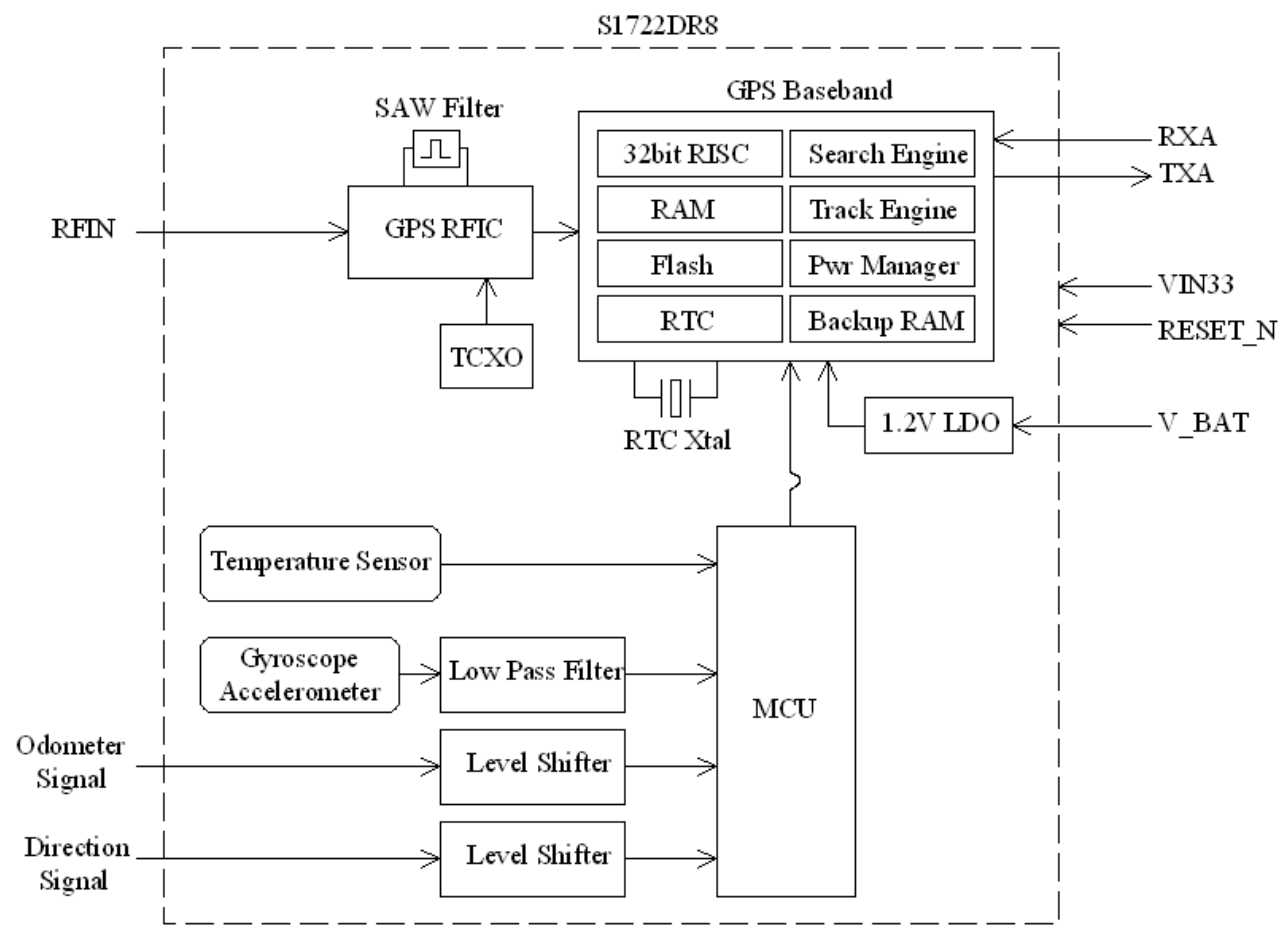

The S1722DR8 features 167 channel GNSS receiver with fast time to first fix and improved -148dBm cold start sensitivity. The superior cold start sensitivity allows it to acquire, track, and get position fix autonomously in difficult weak signal environment. The receiver's -161dBm tracking sensitivity allows continuous position coverage in nearly all application environments. The high performance search engine is capable of testing 16,000,000 time-frequency hypotheses per second, offering industry-leading signal acquisition and TTFF speed.

The receiver is suitable for in vehicle car navigation system that requires high performance continuous navigation, low power, and low cost.

POWER SUPPLY REQUIREMENT

S1722DR8 requires a stable power supply, avoid ripple on VCC33 pin ($<50\text{mVpp}$). Power supply noise can affect the receiver's sensitivity. Bypass capacitors should be placed close to the module VCC33 pin, with values adjusted depending on the amount and type of noise present on the supply line.

BACKUP SUPPLY

The purpose of backup supply voltage pin (VBAT) is to keep the SRAM memory and the RTC powered when the module is powered down. This enables the module to have a faster time-to-first-fix when the module is powered on again. DR calibration data is also kept in this SRAM. If VBAT is not maintained when main power is removed, the receiver will need to go through auto calibration process before DR could take effect every time it's powered on. The backup current drain is less than $10\mu\text{A}$. In normal powered on state, the internal processor access the SRAM and current drain is higher in active mode

ANTENNA CONSIDERATION

3.3V active antenna with 25dB ~ 28dB gain and noise figure less than 2dB can be used.

Choose GPS active antenna for S1722DR8.

Choose GPS/GLONASS active antenna for S1722DR8-GL.

CALIBRATION of DR

S1722DR8 performs calibration of gyro bias and odometer scale automatically using GPS. Customer is not required to perform calibration at installation.

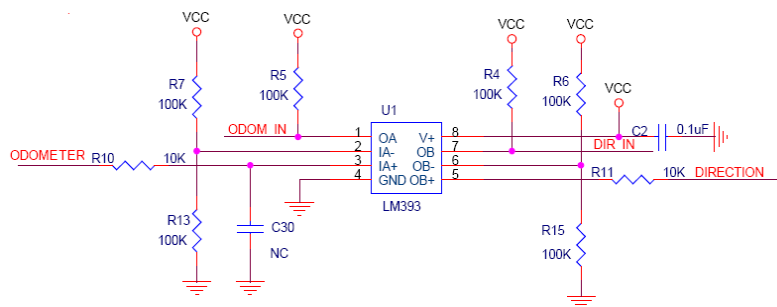

For product testing or benchmarking, the following procedure steps can achieve efficient calibration quickly after a short period of time:

1. Find a open sky place.
 2. Start S1722DR8 and stand still for 60 seconds until position fix is achieved.
 3. Drive straight for 500m at speed of at least 40km/hr.
 4. For next 3 minutes, drive straight and make at least 360-deg turns (either two 90-degrees left turns and right turns, or four left turns, or four right turns) then drive straight for at least another 300m.
-

APPLICATION CIRCUIT

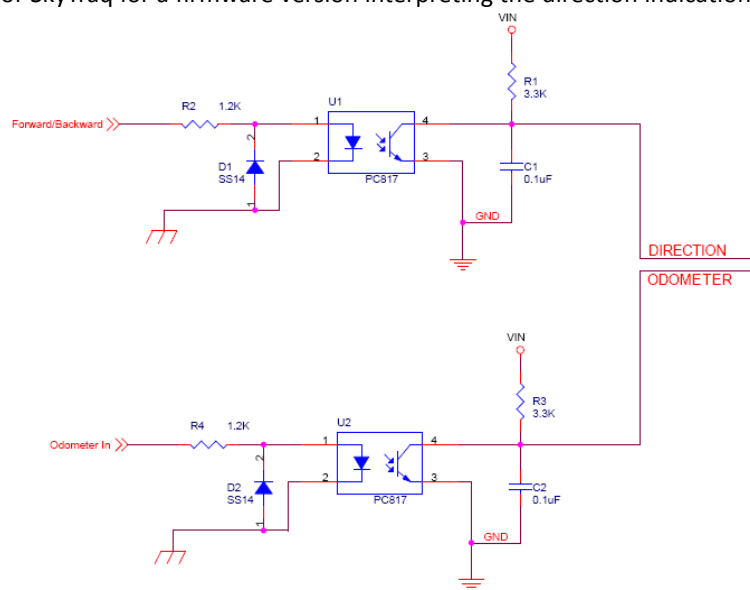

There are already LM393-based level shifters within the S1722DR8 module, the odometer and forward/reverse signal can be directly applied to the module.

For applications that has no forward/reverse indication signal, simply ground the forward/reverse direction input.

For application that has forward/reverse direction inverted, opto-coupler interface shown below may be used. Or can also contact distributor or SkyTraq for a firmware version interpreting the direction indication signal inverted.
